

Opis choroby *

Definicja

A rare mixed neuronal-glia tumor characterized by a supratentorial space-occupying lesion in periventricular location, often with prominent cystic change. The histological hallmark of this low-grade neoplasm is its pseudopapillary appearance with a single layer of cuboidal cells around hyalinized blood vessels, associated with sheets or focal collections of neuronal cells. Clinical presentation is variable and non-specific, most frequently with headache and seizures. Prognosis is favorable after complete resection.
