

Opis choroby *

Definicja

Dirofilariasis is a form of filariasis (see this term), caused by the filarial nematode of the genus *Dirofilaria* (including *Dirofilaria repens*, *Dirofilaria immitis*), which is transmitted by mosquitoes. The disease is characterized by the presence of subcutaneous nodules (or a conjunctival form that develops slowly and that can be painless to tender), edema and erythema at the site of parasite localization, a feeling of 'crawling' under the skin, and the "Calabar" swelling (similar to that in loiasis (see this term). The latter may last a few days and recurrences are possible. Common localizations of dirofilaria are head and neck, most commonly in the periorbital region, the limbs and trunk.
